Abstract

Over the past decade, sustainable or “green” innovation has occupied a top-ranking position on the agenda of many firms. Sustainable innovation can be broadly defined as an innovation that has to consider environmental and social issues as well as the needs of future generations. Although sustainable innovation provides considerable new opportunities for companies it goes along with an increased complexity and possible “traps”. This in turn requires certain organizational routines and capabilities to deal with the upcoming challenges. We explore what the specific driving forces are that lead firms to innovate in a sustainable development domain and that lead towards a build-up of sustainable innovation capabilities. We test them empirically for more than 1,100 firms in Germany. We find that firms need to invest in internal absorptive capacities and draw both broadly and deeply from external impulses for innovation. In that sense, investments in employee training are more important than technological R&D expenditures.

Keywords: Sustainable innovation, absorptive capacity, environmental pressure, capability development

The authors thank … for invaluable comments and discussions.
1 Introduction

Over the past decade, sustainable or “green” innovation has occupied a top-ranking position on the agenda of many firms. This has partly been driven by prominent failures like Shell’s Brent Spar experience or Nike and the Asian “sweatshops”. Sustainable innovation can be broadly defined as an innovation that considers environmental and social issues as well as the needs of future generations. Therefore, sustainable innovation is generally perceived to be more challenging than market innovation (Hall and Vredenburg, 2003). In this respect, sustainable innovation turns out to have two facets. The first one is pressure-driven: Adopting responsible corporate behavior is the result of increasing pressures that companies are facing from their stakeholders, including governments or non-governmental organizations (NGOs) (Christmann and Taylor, 2002; Ottman et al., 2006). The second one is demand-driven: Various stakeholders and most importantly customers, to an increasing extent, have set out to demand products that have been produced in a sustainable way, i.e. in an eco-efficient process, consuming less resources and energy, reducing environmental stress and improving health and safety conditions for employees as well as for customers, the local community or society in general. In this context, customers can react with extreme aggressiveness resulting even in boycotts of certain products or services. At the same time, customers seem to clearly appreciate the firms that are known for their sustainable development strategies or for their reputation in terms of sustainable conduct. Many studies, such as Rindova et al., 2005, have shown that a firm’s reputation can create competitive advantage since reputation constitutes a substantial part of the perceived product or service utility. An indication for this might be the development of the Dow Jones Sustainability Index which tracks the financial performance of the leading sustainability-driven companies worldwide. Since 2001, the index has constantly outperformed a global reference index.¹

In order to comply with pressures from stakeholders on the one hand and to satisfy new customer demands on the other hand, many firms start considering an integration of sustainable development practices and a review of their established business models. Early attempts directed at an improvement of corporate reputation included the establishment of sustainability offices or the publication of sustainability reports (Hall and Vredenburg, 2003). Apart from public relations efforts, companies have also increasingly switched from conforming with regulations to becoming environmentally proactive (Berry and Rondinelli, 1998). They want to become more environmentally responsive. While for the period of the 1960s and seventies companies undertook major efforts to repair environmental damages, they were trying to conform to the increasing extent of environmental regulation during the 1980s. In the nineties, companies were adopting a more proactive environmental policy. Nowadays, sustainable innovation practices are considered an integral part of successful management (Ketata and McIntyre, 2006). But this also implies that a simple public relations-

¹ See http://www.sustainability-indexes.com
A driven approach to sustainable innovation might not be enough as it does not provide sufficient clues for differentiation in the marketplace.

Although sustainable innovation provides considerable new opportunities for companies it goes along with an increased complexity and possible “traps” (Hall and Vredenburg, 2003). This in turn requires certain organizational routines and capabilities to deal with the upcoming challenges. Rooted in the capability based view of the firm, we hypothesize that firms capable of realizing such innovation will have developed certain skills and competencies enabling them to respond to stakeholders’ pressures and demands and – as a consequence – to gain a head start over competitors (Eisenhardt and Martin, 2000; Hoopes et al., 2003). It remains unclear, however, how these sustainable innovation capabilities are developed. We investigate these processes and propose that sustainable innovation capabilities are the result of external demands and fitting internal absorptive capacities to leverage them.

The objective of this paper is twofold: We extend existing literature by investigating this research question both theoretically and empirically. As Helfat and Peteraf (2003: 997) noted, “it is difficult to fully explain how firms use resources and capabilities to create a competitive advantage”, we will provide recommendations on how to develop sustainable innovation capabilities. Important findings in the field have been derived from case studies or based on small samples (see for example Christmann, 2000; Hall and Vredenburg, 2003; Hart and Milstein, 1999). We are able to provide empirical evidence for more than 1,100 German firms and their innovation activities. The remainder of this paper is designed as follows. Section 2 presents our conceptual considerations by focusing on the specifics of sustainable innovation and how sustainable innovation capabilities emerge. The subsequent section 3 develops a set of hypotheses that will be tested in our empirical study (section 4). Section 5 the results of this quantitative analysis followed by discussion and recommendations in section 6. Section 7 closes with limitations and an outlook on future research.

2 Deliberate learning and sustainable innovation capabilities

2.1 The specifics of sustainable innovation

Unique knowledge can be considered a firm’s most valuable asset for generating competitive advantage (Liebeskind, 1996) as it provides firms with the necessary platform to decide which resources or capabilities to deploy, develop or discard as their environment changes (Ndofor and Levitas, 2004). This perspective is typically summarized as the knowledge based view of the firm (Grant, 1996). We suggest that the knowledge required for sustainable innovation is different because it entails additional layers of complexity and uncertainty.

Complex knowledge differs from simple knowledge in the amount of additional, factual information that is required to transfer and understand it fully and accurately (Bhagat et al., 2002). Sustainable innovation is related to environmental, social and economic domains (Hall
and Vredenburg, 2003). In that sense, sustainable innovation adds a broader, systematic perspective to the meaning of “sustainable” competitive advantage by incorporating the interests and needs of all parties involved; including not just shareholders but also employees, customers, local communities, regulators and advocacy groups (Gable and Shireman, 2004). The latter is an important aspect of sustainable innovation. The ability of non-governmental organizations (NGOs) to mobilize and publicize through modern communication technology has given them considerable clout on various issues ranging from food standards to child labor (Brugmann and Prahalad, 2007). These organizations have often resorted to attacking individual market leading firms publicly with indirect repercussions for the industry as a whole. According to Hall and Vredenburg, 2003, social views of a technological innovation are extremely subjective, depend upon various stakeholder groups and change constantly. Some authors have captured this multidimensionality of sustainable innovation as a shift from the traditional one-dimensional profit company target system towards a “triple bottom line” (Elkington, 1998). The latter adds social/ethical and environmental performance measures to traditional profit maximizing goals (Vanclay, 2004). In its simplest form this paradigm change has the potential to safe resources and hence costs, reduce a company’s exposure to risks from publicized malpractices (e.g. resulting in consumer boycotts) and builds a favorable reputation that materializes as respect, trust and confidence (Dowling, 2004; Edelstein, 2004). However, this comprehensive target system is not very precise. Vanclay (2004), for example, presents 11 different descriptions of the triple bottom line ranging from “profit, people, planet” to “landscapes, lifestyles, livelihoods.” Hence, the complexity of sustainable innovation stems from a multitude of external demands from various stakeholders with varying agendas. This makes it challenging to access and assess their knowledge comprehensively because knowledge creation, organization and transfer depends heavily on the commitment and belief patterns of both holders and recipients (Nonaka, 1994).

These layers of complexity resonate inside the company. Sustainable programs typically require a broader scope as they are related to different functional dimensions, i.e. spanning the human resource department, the R&D department, procurement, production and sales (Noci and Verganti, 1999b). In fact, they can involve nearly all organizational functions as well as the whole supply chain. Management expertise is of particular importance as sustainable innovation projects and conventional innovation management strategies are not fully applicable (Hall and Vredenburg, 2003). This involves adequate communication with and training of employees as this domain needs to be integrated into their daily activities in order to avoid resistance and frustration. Ketata and McIntyre, 2006, find that a lack of understanding for the benefits of innovating in the sustainable development domain among employees leads them to resist these projects.

Dealing with complex knowledge leads to causal uncertainty (Bhagat et al., 2002) which implies more frequent mistakes in sustainable innovation activities. Irredeemable investments into the wrong projects exhibit a considerable economic risk (Balachandra and Brockhoff, 1995). Besides, sustainability management is associated with a significant financial commitment (Walley and Whitehead, 1994). Sustainable innovation is more expensive than traditional innovation since the former involves almost the whole company structure, and implies investing in a whole set of different technologies that might considerably exceed the
scope of a firm’s competencies (Shrivastava, 1995). Moreover, the pay-offs from sustainable innovation may not immediately translate into monetary benefits but are often intangible and related to long-term objectives (e.g. reputation building). In contrast to that, the pressures for efficiency and profitability of the innovation process are very direct, immediate and specific.

2.2 Learning processes and capability build-up

Looking at the time frame that it took companies to start developing capabilities for dealing with sustainable innovation concerns it becomes clear that the creation of such capabilities necessarily involves a deliberate learning process. Firms obviously need to understand at first the challenges of regulation and new demands in order to develop targeted capabilities that leverage competitive advantage. The knowledge (and capability\(^2\)) based view of the firm complements traditional industry analysis in that internal and external factors have to be considered to understand the sources of such competitive advantage (Amit and Schoemaker, 1993; Sirmon et al., 2007). Several studies argue that capabilities cannot be investigated without considering their relevant context (Atuahene-Gima and Haiyang, 2004; Brush and Artz, 1999): the “when, where and how” knowledge resources and capabilities translate into competitive advantage (Priem and Butler, 2001). We follow this stream of literature by discussing the roots of sustainable innovation capabilities and their relevant context.

We argue that the mechanism behind the build-up of sustainable innovation capabilities can be regarded as a continuous and deliberate learning process (Zollo and Winter, 2002). This process describes a firm’s systematic methods for a modification of its operating routines. Such routines constitute stable patterns of organizational behavior and reaction on internal or external stimuli. On the one hand, routines define predictable as well as interrelated organizational actions e.g. on the production process at globally dispersed production sites. On the other hand, a routine may also initiate the introduction of certain environmental or health standards in global production processes. This second type of routines is typically referred to as search routines (Nelson and Winter, 1982). They deal with changes in the existing set of operating routines and can hence be seen as constitutive of sustainable innovation capabilities.

In a relatively stable environment, operating routines superior to those of competitors can be a source of sustainable competitive advantage. It may even be sufficient to rely on discrete and sporadic changes and improvements in the set of operating routines that may result from a tacit accumulation of experience. However, when the environment turns more demanding in that new regulation is imposed from different regulatory bodies or stakeholders assert certain claims regarding the adoption of sustainable development practices, a stable set of routines might no longer be sufficient. Systematic efforts are needed to track the environment and dynamically adjust routines. This is where sustainable innovation capabilities enter the game.

\(^2\) Capabilities are organizational processes which bundle strategic knowledge resources into unique combinations and constitute superior performance themselves. This follows the basic rationale that competitive advantage does not only arise from the possession of such resources but also from the way in which they are used (Penrose, 1959).
A failure to develop such capabilities that leverage the value of a firm’s resources in a more demanding environment would otherwise turn once established core competencies into core rigidities (Leonard-Barton, 1992). A simple accumulation of experience and knowledge resulting from a repeated execution of routines combined with a trial-and-error proceeding will therefore not be enough for a build-up of sustainable innovation capabilities. This process necessarily needs to culminate in knowledge articulation and knowledge codification. The following section centers around these two aspects within the learning process to derive our hypotheses.

3 Hypothesis development

Knowledge articulation evolves from discursive actions between individuals and groups in the execution of organizational tasks (Levitt and March, 1988; Levinthal and March, 1993). Expressing opinions and individual viewpoints, challenging them and mutually understanding causal linkages – especially in the presence of ambiguities – are a pre-requisite for making implicit or tacit knowledge explicit and hence for enabling collective learning efforts. Knowledge from relevant stakeholders has to be made available throughout the company in order to adjust operating routines accordingly and to spread successful action-performance links within the whole organization. Sirmon et al. (2007) have suggested that the effectiveness of this step also depends on environmental munificence. The varying munificence of environments might critically affect the potential value of a firm’s resources and capabilities. Moreover, munificent environments can support the growth of resources within firms by providing access to complementary, external resources (Baum and Wally, 2003). We argue that sustainable innovation capabilities stem from investments in internal absorptive capacities that reflect the munificence of the environment.

3.1 Absorptive capacities for sustainable innovation

Learning processes are built around a firm’s ability to extract relevant market knowledge and integrate it into new products and services as well as into the whole organization. While market impulses are available to all competitors, firms can differentiate themselves through their expertise in synthesizing this information, integrating and combining it with existing knowledge (Henderson and Cockburn, 1994; Kogut and Zander, 1992). An important stream of literature has summarized these capabilities as absorptive capacity (Cohen and Levinthal, 1989b, 1990a): a firm’s ability to identify, assimilate and exploit knowledge from the environment. This differentiation corresponds with the three learning mechanisms in organizational capability development – experience accumulation, knowledge articulation and knowledge codification – but puts a stronger emphasis on exploiting and capitalizing acquired knowledge. Several studies have linked absorptive capacity to superior firm performance (Landry and Amara, 2002; Love and Roper, 2004; Nadiri, 1993). Absorptive capacities are typically accumulated as a by-product of firms’ innovation activities and hence difficult to acquire, imitate or substitute (Amit and Schoemaker, 1993).
Cohen and Levinthal, 1989a, 1990b follow the rationale that absorptive capacities are developed by performing R&D activities which stresses the technological aspect of absorptive capacity. Technological advances are an obvious driver of innovation. However, they are especially relevant for sustainable innovation activities as they often times appear outside of a firms’ traditional field of technological expertise (Shrivastava, 1995). Other studies have extended the absorptive capacity concept towards employees' level of education and academic achievement (Rothwell and Dodgson, 1991). In addition, motivational factors have been found to be important for activating these capacities (Lane and Lubatkin, 1998; Lord and Ranft, 2000). The discussion on the specifics of sustainable innovation has shown that it has both a technological and social facet. Hence we develop two hypotheses:

Hypothesis Ia: Investments in technological absorptive capacities increase the likelihood of sustainable innovation.

Hypothesis Ib: Investments in the education of employees and their individual absorptive capacities increase the likelihood of sustainable innovation.

3.2 Munificent environments for sustainable innovation

Sustainable innovation activities add new layers of complexity to a firms’ innovation process (Noci and Verganti, 1999a). As the pool of relevant stakeholders and therefore knowledge sources increases firms need to broaden their spectrum for potential innovation impulses. Zahra and George (2002) introduce the distinction between potential and realized absorptive capacity. Put simply, they envision absorptive capacity as a funnel with a large opening for taking in a broad variety of diverse ideas with potential value. These have to be narrowed down, prioritized and codified to facilitate efficient assimilation and exploitation processes (Jansen et al., 2005). Complex knowledge requires the transfer and processing of additional knowledge that puts the core item into perspective. It may stem from technological, market or regulatory factors. This necessitates their integration in existing products and processes which depends heavily on available competencies. Early customer involvement has been found to be especially important for the market success of sustainable innovations (Hall and Kerr, 2003; Heiskanen et al., 2005). However, important impulses for innovation can also be technologically or legally induced. Certain companies are more open to new ideas than others. Indeed, specific features related to the company help it to be more open to these ideas. In this context, the culture of the company and its customs have an important influence. In fact, an open culture for innovation is a necessary condition for the firm to recognize the need to innovate (Ekvall and Ryhammar, 1998; Lester, 1998; van der Panne et al., 2003). Openness prevents firms from missing important dynamics in their environment (Chesbrough, 2003) and enables them to predict future trends more accurately (Cohen and Levinthal, 1994). We propose:

Hypothesis IIa: As the diversity of external knowledge inside the firm increases sustainable innovation becomes more likely.
However, Laursen and Salter, 2006 contrast the concept of breadth in knowledge sourcing with the necessary depth. There is a need for focus as company’s information processing capacities are limited. A vast amount of ideas impedes selection and exploitation processes (Koput, 1997). Hence, we derive:

Hypothesis IIb: As the depth of external knowledge inside the firm increases sustainable innovation becomes more likely.

After all, it would be shortsighted to perceive sustainable innovation as a purely voluntary endeavor. Governmental and regulatory agencies play an important role in influencing sustainable innovation. Hall and Vredenburg, 2003, stress this aspect when discussing the introduction of new laws that sanction those that are harmful to the environment and to the population. Following the munificence rationale, we argue that regulations can be supportive in nature, i.e. in the form of subsidies, or based on sanctioning mechanisms (Abdul-Gafaru, 2006). We therefore suggest:

Hypothesis IIIa: As regulatory demands increase sustainable innovation becomes more likely.

Hypothesis IIIb: As financial support from the government increases sustainable innovation becomes more likely.

4 Empirical study

4.1 Data

For the empirical part of this analysis we use cross section data from a survey on the innovation behavior of German enterprises called the “Mannheim Innovation Panel” (MIP). The survey is conducted annually by the Centre for European Economic Research (ZEW) on behalf of the German Federal Ministry of Education and Research. The methodology and questionnaire used by the survey, which is targeted at enterprises with at least five employees, are the same as those used in the Community Innovation Survey (CIS), conducted every four years by Eurostat. For our analysis we use the 2005 survey, in which data was collected on the innovation activities of enterprises during the three-year period 2002-2004. About 4,500 firms in manufacturing and services responded to the survey and provided information on their innovation activities.³ We utilize this data to operationalize the concepts presented above. Non-innovating firms were excluded from our analysis, because most variables can only be constructed for firms with innovation activities. Besides, we narrow our analysis to the manufacturing sector. As a result we retain a final sample of 1,124 firm observations.

³ The sample was drawn using the stratified random sample technique. For a more detailed description of the dataset and the survey see Rammer et al., 2005.
CIS surveys are self-reported and largely qualitative which raises quality issues with regards to administration, non-response and response accuracy (for a recent discussion see Criscuolo et al., 2005). First, our CIS survey was administered via mail which prevents certain shortcomings and biases of telephone interviews (for a discussion see Bertrand and Mullainathan, 2001). The multinational application of CIS surveys adds extra layers of quality management and assurance. CIS surveys are subject to extensive pre-testing and piloting in various countries, industries and firms with regards to interpretability, reliability and validity (Laursen and Salter, 2006). Secondly, a comprehensive non-response analysis of more than 4,000 firms showed no systematic distortions between responding and non-responding firms with respect to their innovation activities. Third, the questionnaire contains detailed definitions and examples to increase response accuracy. Longhand questions (e.g. “Please describe your most important product innovation briefly”) allow robustness checks for multiple choice answers.

In conclusion, the major advantages of CIS surveys are that they provide direct, importance-weighted measures for a comprehensive set of sources (Criscuolo et al., 2005). On the downside, this information is self-reported. Heads of R&D departments or innovation management are asked directly if and how they are able to generate innovations. This immediate information on processes and outputs can complement traditional measures for innovation such as patents (Kaiser, 2002; Laursen and Salter, 2006).

4.2 Variables

Measuring sustainable innovation

The previous theoretical discussion made it clear that our research question touches a multifaceted construct. It cannot be readily observed. Hence we rely on qualitative, self-reported but importance-weighted answers to a question on the outcomes of a firm’s innovation activities. Respondents are asked to assess the importance of these outcomes on a 4 point Likert scale ranging from “not relevant” to “high”. We rely on three different outcomes: Reduction in resource/energy consumption, reduction of economic stress and improvement of health/safety. We construct a sustainability index based on these ratings through principal factor analysis and retain a single factor with an eigenvalue larger than one (2.16; Cronbach’s alpha scale reliability coefficient: 0.71; Kaiser-Meyer-Olkin measure of sampling adequacy: 0.71). A higher index value indicates that firms assign higher importance to all three sustainable components of their innovation activities and vice versa. It will serve as the dependent variable in our empirical study.

Measuring absorptive capacity

Absorptive capacities are not a tangible concept but rather a combination of different competencies and capabilities. Hence, companies cannot be easily surveyed to estimate the degree to which they possess these absorptive capacities. Cohen and Levinthal, 1989a, 1990b, follow the rationale that absorptive capacities are developed by performing R&D activities.
We follow their suggestion and introduce R&D intensity (share of R&D expenditures of sales) to our model. Besides, investments in employees’ level of education and academic achievement have been recognized as an important indicator for a firms’ absorptive capacity (Rothwell and Dodgson, 1991). We capture this item through the training expenditure per employee. Absorptive capacities are generally accumulated over time. Hence, consistent R&D engagements should produce superior results to sporadic ones. We therefore include a dummy variable indicating whether the firm performs continuous R&D activities.

**Measuring environmental munificence**

Laursen and Salter, 2006 suggest a differentiation between breadth and depth of external innovation impulses by relying on the importance weighted information obtained through surveys. We are able to obtain information on a comprehensive list of potential sources for innovation and their importance. These nine options are suppliers, customers, competitors, consultancies, universities, public research institutions, conferences, scientific journals and trade associations. Following Laursen and Salter, 2006, we measure a firm’s breadth of external innovation inputs as the number of different sources used (from 0 to 9) and depth as the number of sources they assigned a high importance to.

With regards to governmental support/pressure, we add dummy variables indicating whether the firm received public funding for their innovation activities and whether it perceived regulatory pressure as an important obstacle to its innovation activities.

**Control variables**

Furthermore, we control for several other factors that may influence the estimation results of our core variables. These control variables capture regional differences (whether the firm is located in East Germany) and a firm’s size (number of employees in logs). We capture the effects from internationalization (share of exports of sales) and remaining industry effects through variables on whether a firm operates in medium high-tech manufacturing (e.g. automotives) or high-tech manufacturing (e.g. medical equipment). A detailed industry breakdown is provided in Appendix A. “Other manufacturing” (e.g. food and tobacco) will be the comparison group for all subsequent steps of the analysis.

**4.3  Descriptive statistics**

Appendix B provides a detailed overview on the characteristics of sustainable innovating firms divided by the median of the sustainability index. On average, firms focus on resource and energy saving sustainable innovation activities followed by health and safety and environmental ones. They rely on a broad set of external sources for innovation (roughly 7) but high importance is just assigned to a single one. Firms with high sustainability index values invest more into the training of their employees and R&D. They feel more pressured by regulatory demands but are not more likely recipients of public R&D funding.
While this prima facie comparison is an early indication for the accuracy of our theoretically derived hypotheses these firms also differ in other important characteristics. They are on average larger, less frequently located in East Germany and high-tech manufacturing industries. Hence, a multivariate analysis is required.

4.4 Model and method

We choose a standard ordinary least squares regression model for estimation. One might argue that the investments in absorptive capacities are already reflected in the sources used (breadth and depth). We add absorptive capacity and munificence variables stepwise to the model and present both results. Effects should be consistent in both models.

5 Results

Table 1 provides the results of the estimation. Our sample consists solely of firms with successful innovation activities. One should bear in mind that we measure differences between them with regards to sustainability but not their general propensity to innovate. Focusing on the model specifications (Model I and its extension II), significant effects are consistent. Adding munificence variables increases the overall fit of the model considerably.

***, **, * indicate significance at the 1%, 5% and 10% level; bootstrapped standard errors

The estimation results reveal that investments into absorptive capacities for sustainable innovation are focused on investing in employees (positive effect of training expenditures) while investments in R&D (negative effect) are detrimental. This result holds both on the firm and the industry level (negative, significant effect on high-tech industry dummy). Therefore, Hypothesis Ia has to be rejected while Ib is supported. Continuous R&D activities often associated with having a dedicated R&D department as a nexus of innovation engagements and learning shows no significant effect. This may be an indication for the multi-functional nature of sustainable innovation (Hall and Vredenburg, 2003).

With regards to the munificence of the environment both the breadth and depth of external innovation sources have a positive significant effect. Hypotheses IIa and IIb can be accepted. Interestingly, the effect of breadth is stronger. Direct regulatory pressure has a significant positive effect on sustainable innovation engagements while public funding produces no significant effect. Hypothesis IIIa is supported while IIIb has to be rejected. Control variables have no significant impact with the exception of firm size propelling sustainable innovation and the already mentioned negative effect in high-tech manufacturing.

6 Discussion and implications

This analysis focuses on the processes that allow firms to develop sustainable innovation capabilities. We suggest conceptually that the knowledge required for successful sustainable innovation capabilities is both more complex and uncertain than for traditional ones. We argue that this needs to be reflected in a firm’s investments in absorptive capacities and the breadth and depth of their learning engagements.
Our findings directly translate into management recommendations on how to strengthen or develop sustainable innovation capabilities. We find strong benefits for investing in the training of employees as opposed to technological R&D. We suggest that the merits of internal R&D may be limited as important technological impulses for sustainable innovation appear outside a firm’s traditional fields of technological expertise (Shrivastava, 1995). Technological breakthroughs in energy storage and batteries for fuel efficient hybrid car production may be a fitting example. Motivated and well trained employees may give firms broader interfaces to deal with a multitude of potential stakeholders in the environment. This includes not only the ability to collect impulses but also to set priorities and choose the crucial ones.

This line of reasoning resonates immediately with our findings on the breadth and depth of innovation impulses. The former represents the potential of ideas for a company while the latter implies boiling them down to a few important ones to act on efficiently (Jansen et al., 2005). Both are important for sustainable innovation capabilities. Apparently, breadth is even more important than depth. We suggest that the dangers from blind spots or betting on the wrong horse are especially pronounced in sustainable innovation. Firms may hedge against long lasting reputation effects from individual failures or malpractices. Finally, we find that firms respond to the traditional mechanisms of regulatory intervention when it comes to sustainable innovation. In that sense, sustainable innovation may not just be a chosen capability but also a mandatory one.

7 Limitations and further research

Our analysis is constrained by certain limitations which may in turn provide new opportunities for other research projects. First, our empirical analysis is limited to Germany. It has a large tradition of societal, political and regulatory awareness for environmental challenges. In fact, Germany has been frequently characterized as a lead market for sustainable innovation (Beise-Zee and Rennings, 2005). However, it may not be representative for other countries with different backgrounds and structures. Hence, we encourage comparative studies. Secondly, our findings on the link between openness for external ideas, internal absorptive capacities and successful sustainable innovation beg more in-depth analysis. Third, we capture only a single point in time. Sustainable innovation, however, follows long-term orientations that should be explored through longitudinal data.
# Appendix

## Appendix A: Industry classification

<table>
<thead>
<tr>
<th>Industry</th>
<th>NACE Code</th>
<th>Industry Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mining and quarrying</td>
<td>10 – 14</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Food and tobacco</td>
<td>15 – 16</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Textiles and leather</td>
<td>17 – 19</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Wood / paper / publishing</td>
<td>20 – 22</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Chemicals / petroleum</td>
<td>23 – 24</td>
<td>Medium high-tech manufacturing</td>
</tr>
<tr>
<td>Plastic / rubber</td>
<td>25</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Glass / ceramics</td>
<td>26</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Metal</td>
<td>27 – 28</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Manufacture of machinery and equipment</td>
<td>29</td>
<td>Medium high-tech manufacturing</td>
</tr>
<tr>
<td>Manufacture of electrical machinery</td>
<td>30 – 32</td>
<td>High-tech manufacturing</td>
</tr>
<tr>
<td>Medical, precision and optical instruments</td>
<td>33</td>
<td>High-tech manufacturing</td>
</tr>
<tr>
<td>Manufacture of motor vehicles</td>
<td>34 – 35</td>
<td>Medium high-tech manufacturing</td>
</tr>
<tr>
<td>Manufacture of furniture, jewellery, sports equipment and toys</td>
<td>36 – 37</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Electricity, gas and water supply</td>
<td>40 – 41</td>
<td>Other manufacturing</td>
</tr>
<tr>
<td>Construction</td>
<td>45</td>
<td>Other manufacturing</td>
